

Abstract of the Disclosure

A system for anonymously initiating communication between system-
5 connected communications devices is provided wherein the initiation of
communication results from comparison and priority matching of profile
information shared between the devices. The system in one aspect
comprises at least two communications devices connected to the system, the
communications devices having at least a microprocessor, a data-input
10 mechanism, a display screen, a wireless local-area-network protocol
application enhanced with short-wave radio communication capability
installed per instance to each of the devices, and a profile comparison and
matching application installed per instance to each of the devices. When any
two of the devices come into short-wave radio range of each other, the
15 devices activated, a wireless local-area-network is established and the in-
range devices swap profiles, which are compared to profiles held locally on
each device such that a profile match registering on at least one device
enables the device matching the profile to signal the sending device of the
matched profile in order to request communication between the devices.
